NAME

ovn-northd - Open Virtual Network central control daemon

SYNOPSIS

ovn-northd [options]

DESCRIPTION

ovn—northd is a centralized daemon responsible for translating the high-level OVN configuration into logical configuration consumable by daemons such as **ovn—controller**. It translates the logical network configuration in terms of conventional network concepts, taken from the OVN Northbound Database (see **ovn—nb**(5)), into logical datapath flows in the OVN Southbound Database (see **ovn—sb**(5)) below it.

OPTIONS

--ovnnb-db=database

The OVSDB database containing the OVN Northbound Database. If the OVN_NB_DB environment variable is set, its value is used as the default. Otherwise, the default is unix:/ovnnb db.sock.

--ovnsb-db= database

The OVSDB database containing the OVN Southbound Database. If the OVN_SB_DB environment variable is set, its value is used as the default. Otherwise, the default is unix:/ovnsb db.sock.

database in the above options must be an OVSDB active or passive connection method, as described in **ovsdb**(7).

Daemon Options

--pidfile[=*pidfile*]

Causes a file (by default, *program.pid*) to be created indicating the PID of the running process. If the *pidfile* argument is not specified, or if it does not begin with /, then it is created in .

If **--pidfile** is not specified, no pidfile is created.

--overwrite-pidfile

By default, when **—pidfile** is specified and the specified pidfile already exists and is locked by a running process, the daemon refuses to start. Specify **—overwrite—pidfile** to cause it to instead overwrite the pidfile.

When **—pidfile** is not specified, this option has no effect.

--detach

Runs this program as a background process. The process forks, and in the child it starts a new session, closes the standard file descriptors (which has the side effect of disabling logging to the console), and changes its current directory to the root (unless **—-no-chdir** is specified). After the child completes its initialization, the parent exits.

--monitor

Creates an additional process to monitor this program. If it dies due to a signal that indicates a programming error (SIGABRT, SIGALRM, SIGBUS, SIGFPE, SIGILL, SIGPIPE, SIGSEGV, SIGXCPU, or SIGXFSZ) then the monitor process starts a new copy of it. If the daemon dies or exits for another reason, the monitor process exits.

This option is normally used with **--detach**, but it also functions without it.

--no-chdir

By default, when **—detach** is specified, the daemon changes its current working directory to the root directory after it detaches. Otherwise, invoking the daemon from a carelessly chosen directory would prevent the administrator from unmounting the file system that holds that directory.

Specifying **—no–chdir** suppresses this behavior, preventing the daemon from changing its current working directory. This may be useful for collecting core files, since it is common behavior to write core dumps into the current working directory and the root directory is not a good directory to use.

This option has no effect when **--detach** is not specified.

--no-self-confinement

By default this daemon will try to self-confine itself to work with files under well-known directories whitelisted at build time. It is better to stick with this default behavior and not to use this flag unless some other Access Control is used to confine daemon. Note that in contrast to other access control implementations that are typically enforced from kernel-space (e.g. DAC or MAC), self-confinement is imposed from the user-space daemon itself and hence should not be considered as a full confinement strategy, but instead should be viewed as an additional layer of security.

--user=user:group

Causes this program to run as a different user specified in *user:group*, thus dropping most of the root privileges. Short forms *user* and *:group* are also allowed, with current user or group assumed, respectively. Only daemons started by the root user accepts this argument.

On Linux, daemons will be granted **CAP_IPC_LOCK** and **CAP_NET_BIND_SERVICES** before dropping root privileges. Daemons that interact with a datapath, such as **ovs-vswitchd**, will be granted three additional capabilities, namely **CAP_NET_ADMIN**, **CAP_NET_BROAD-CAST** and **CAP_NET_RAW**. The capability change will apply even if the new user is root.

On Windows, this option is not currently supported. For security reasons, specifying this option will cause the daemon process not to start.

Logging Options

 $-\mathbf{v}[spec]$

--verbose=[spec]

Sets logging levels. Without any *spec*, sets the log level for every module and destination to **dbg**. Otherwise, *spec* is a list of words separated by spaces or commas or colons, up to one from each category below:

- A valid module name, as displayed by the **vlog/list** command on **ovs-appctl**(8), limits the log level change to the specified module.
- syslog, console, or file, to limit the log level change to only to the system log, to the console, or to a file, respectively. (If --detach is specified, the daemon closes its standard file descriptors, so logging to the console will have no effect.)

On Windows platform, **syslog** is accepted as a word and is only useful along with the **—-syslog-target** option (the word has no effect otherwise).

• **off**, **emer**, **err**, **warn**, **info**, or **dbg**, to control the log level. Messages of the given severity or higher will be logged, and messages of lower severity will be filtered out. **off** filters out all messages. See **ovs-appctl**(8) for a definition of each log level.

Case is not significant within spec.

Regardless of the log levels set for **file**, logging to a file will not take place unless **--log-file** is also specified (see below).

For compatibility with older versions of OVS, any is accepted as a word but has no effect.

--verbose

Sets the maximum logging verbosity level, equivalent to --verbose=dbg.

- -vPATTERN:destination:pattern
- --verbose=PATTERN:destination:pattern

Sets the log pattern for *destination* to *pattern*. Refer to **ovs-appctl**(8) for a description of the valid syntax for *pattern*.

-vFACILITY: facility

--verbose=FACILITY:facility

Sets the RFC5424 facility of the log message. *facility* can be one of **kern**, **user**, **mail**, **daemon**, **auth**, **syslog**, **lpr**, **news**, **uucp**, **clock**, **ftp**, **ntp**, **audit**, **alert**, **clock2**, **local0**, **local1**, **local2**, **local3**, **local4**, **local5**, **local6** or **local7**. If this option is not specified, **daemon** is used as the default for the local system syslog and **local0** is used while sending a message to the target provided via the **—syslog—target** option.

--log-file[=file]

Enables logging to a file. If *file* is specified, then it is used as the exact name for the log file. The default log file name used if *file* is omitted is /usr/local/var/log/ovn/program.log.

--syslog-target=host:port

Send syslog messages to UDP *port* on *host*, in addition to the system syslog. The *host* must be a numerical IP address, not a hostname.

--syslog-method=method

Specify *method* as how syslog messages should be sent to syslog daemon. The following forms are supported:

- libc, to use the libc syslog() function. Downside of using this options is that libc adds
 fixed prefix to every message before it is actually sent to the syslog daemon over /dev/log
 UNIX domain socket.
- unix:file, to use a UNIX domain socket directly. It is possible to specify arbitrary message format with this option. However, rsyslogd 8.9 and older versions use hard coded parser function anyway that limits UNIX domain socket use. If you want to use arbitrary message format with older rsyslogd versions, then use UDP socket to localhost IP address instead.
- udp:ip:port, to use a UDP socket. With this method it is possible to use arbitrary message format also with older rsyslogd. When sending syslog messages over UDP socket extra precaution needs to be taken into account, for example, syslog daemon needs to be configured to listen on the specified UDP port, accidental iptables rules could be interfering with local syslog traffic and there are some security considerations that apply to UDP sockets, but do not apply to UNIX domain sockets.
- **null**, to discard all messages logged to syslog.

The default is taken from the **OVS_SYSLOG_METHOD** environment variable; if it is unset, the default is **libc**.

PKI Options

PKI configuration is required in order to use SSL for the connections to the Northbound and Southbound databases.

-**p** privkey.pem

--private-key=privkey.pem

Specifies a PEM file containing the private key used as identity for outgoing SSL connections.

-c cert.pem

--certificate=cert.pem

Specifies a PEM file containing a certificate that certifies the private key specified on **-p** or **--private-key** to be trustworthy. The certificate must be signed by the certificate authority (CA) that the peer in SSL connections will use to verify it.

-C cacert.pem

--ca-cert=cacert.pem

Specifies a PEM file containing the CA certificate for verifying certificates presented to this program by SSL peers. (This may be the same certificate that SSL peers use to verify the certificate specified on **–c** or **––certificate**, or it may be a different one, depending on the PKI design in use.)

-C none

--ca-cert=none

Disables verification of certificates presented by SSL peers. This introduces a security risk, because it means that certificates cannot be verified to be those of known trusted hosts.

Other Options

--unixctl=socket

Sets the name of the control socket on which *program* listens for runtime management commands (see *RUNTIME MANAGEMENT COMMANDS*, below). If *socket* does not begin with /, it is interpreted as relative to . If **—unixctl** is not used at all, the default socket is */program.pid.ctl*, where *pid* is *program*'s process ID.

On Windows a local named pipe is used to listen for runtime management commands. A file is created in the absolute path as pointed by *socket* or if **—unixctl** is not used at all, a file is created as *program* in the configured *OVS_RUNDIR* directory. The file exists just to mimic the behavior of a Unix domain socket.

Specifying **none** for *socket* disables the control socket feature.

-h

--help Prints a brief help message to the console.

-V

--version

Prints version information to the console.

RUNTIME MANAGEMENT COMMANDS

ovs-appctl can send commands to a running **ovn-northd** process. The currently supported commands are described below.

exit Causes **ovn-northd** to gracefully terminate.

pause Pauses the ovn-northd operation from processing any Northbound and Southbound database changes. This will also instruct ovn-northd to drop any lock on SB DB.

resume Resumes the ovn-northd operation to process Northbound and Southbound database contents and generate logical flows. This will also instruct ovn-northd to aspire for the lock on SB DB.

is-paused

Returns "true" if ovn-northd is currently paused, "false" otherwise.

status Prints this server's status. Status will be "active" if ovn-northd has acquired OVSDB lock on SB DB, "standby" if it has not or "paused" if this instance is paused.

ACTIVE-STANDBY FOR HIGH AVAILABILITY

You may run **ovn-northd** more than once in an OVN deployment. When connected to a standalone or clustered DB setup, OVN will automatically ensure that only one of them is active at a time. If multiple instances of **ovn-northd** are running and the active **ovn-northd** fails, one of the hot standby instances of **ovn-northd** will automatically take over.

Active-Standby with multiple OVN DB servers

You may run multiple OVN DB servers in an OVN deployment with:

- OVN DB servers deployed in active/passive mode with one active and multiple passive ovsdb-servers.
- **ovn-northd** also deployed on all these nodes, using unix ctl sockets to connect to the local OVN DB servers.

In such deployments, the ovn-northds on the passive nodes will process the DB changes and compute logical flows to be thrown out later, because write transactions are not allowed by the passive ovsdb-servers. It

results in unnecessary CPU usage.

With the help of runtime management command **pause**, you can pause **ovn-northd** on these nodes. When a passive node becomes master, you can use the runtime management command **resume** to resume the **ovn-northd** to process the DB changes.

LOGICAL FLOW TABLE STRUCTURE

One of the main purposes of **ovn-northd** is to populate the **Logical_Flow** table in the **OVN_Southbound** database. This section describes how **ovn-northd** does this for switch and router logical datapaths.

Logical Switch Datapaths

Ingress Table 0: Admission Control and Ingress Port Security - L2

Ingress table 0 contains these logical flows:

- Priority 100 flows to drop packets with VLAN tags or multicast Ethernet source addresses.
- Priority 50 flows that implement ingress port security for each enabled logical port. For logical ports on which port security is enabled, these match the inport and the valid eth.src address(es) and advance only those packets to the next flow table. For logical ports on which port security is not enabled, these advance all packets that match the inport.

There are no flows for disabled logical ports because the default-drop behavior of logical flow tables causes packets that ingress from them to be dropped.

Ingress Table 1: Ingress Port Security - IP

Ingress table 1 contains these logical flows:

- For each element in the port security set having one or more IPv4 or IPv6 addresses (or both),
 - Priority 90 flow to allow IPv4 traffic if it has IPv4 addresses which match the **inport**, valid **eth.src** and valid **ip4.src** address(es).
 - Priority 90 flow to allow IPv4 DHCP discovery traffic if it has a valid **eth.src**. This is necessary since DHCP discovery messages are sent from the unspecified IPv4 address (0.0.0.0) since the IPv4 address has not yet been assigned.
 - Priority 90 flow to allow IPv6 traffic if it has IPv6 addresses which match the **inport**, valid **eth.src** and valid **ip6.src** address(es).
 - Priority 90 flow to allow IPv6 DAD (Duplicate Address Detection) traffic if it has a valid **eth.src**. This is is necessary since DAD include requires joining an multicast group and sending neighbor solicitations for the newly assigned address. Since no address is yet assigned, these are sent from the unspecified IPv6 address (::).
 - Priority 80 flow to drop IP (both IPv4 and IPv6) traffic which match the inport and valid eth.src.
- One priority—0 fallback flow that matches all packets and advances to the next table.

Ingress Table 2: Ingress Port Security - Neighbor discovery

Ingress table 2 contains these logical flows:

- For each element in the port security set,
 - Priority 90 flow to allow ARP traffic which match the **inport** and valid **eth.src** and **arp.sha**. If the element has one or more IPv4 addresses, then it also matches the valid **arp.spa**.
 - Priority 90 flow to allow IPv6 Neighbor Solicitation and Advertisement traffic which match the inport, valid eth.src and nd.sll/nd.tll. If the element has one or

more IPv6 addresses, then it also matches the valid **nd.target** address(es) for Neighbor Advertisement traffic.

- Priority 80 flow to drop ARP and IPv6 Neighbor Solicitation and Advertisement traffic which match the **inport** and valid **eth.src**.
- One priority—0 fallback flow that matches all packets and advances to the next table.

Ingress Table 3:from-lportPre-ACLs

This table prepares flows for possible stateful ACL processing in ingress table ACLs. It contains a priority–0 flow that simply moves traffic to the next table. If stateful ACLs are used in the logical datapath, a priority–100 flow is added that sets a hint (with reg0[0] = 1; next;) for table Pre-stateful to send IP packets to the connection tracker before eventually advancing to ingress table ACLs. If special ports such as route ports or localnet ports can't use ct(), a priority–110 flow is added to skip over stateful ACLs.

This table also has a priority-110 flow with the match **eth.dst** == E for all logical switch datapaths to move traffic to the next table. Where E is the service monitor mac defined in the **options:svc_monitor_mac** colum of **NB** Global table.

Ingress Table 4: Pre-LB

This table prepares flows for possible stateful load balancing processing in ingress table **LB** and **Stateful**. It contains a priority–0 flow that simply moves traffic to the next table. Moreover it contains a priority–110 flow to move IPv6 Neighbor Discovery traffic to the next table. If load balancing rules with virtual IP addresses (and ports) are configured in **OVN_Northbound** database for a logical switch datapath, a priority–100 flow is added for each configured virtual IP address *VIP*. For IPv4 *VIPs*, the match is **ip && ip4.dst** == *VIP*. For IPv6 *VIPs*, the match is **ip && ip6.dst** == *VIP*. The flow sets an action **reg0[0]** = **1**; **next**; to act as a hint for table **Pre–stateful** to send IP packets to the connection tracker for packet de-fragmentation before eventually advancing to ingress table **LB**. If controller_event has been enabled and load balancing rules with empty backends have been added in **OVN_Northbound**, a 130 flow is added to trigger ovn-controller events whenever the chassis receives a packet for that particular VIP. If **event–elb** meter has been previously created, it will be associated to the empty lb logical flow

This table also has a priority-110 flow with the match **eth.dst** == E for all logical switch datapaths to move traffic to the next table. Where E is the service monitor mac defined in the **options:svc_monitor_mac** colum of **NB_Global** table.

Ingress Table 5: Pre-stateful

This table prepares flows for all possible stateful processing in next tables. It contains a priority-0 flow that simply moves traffic to the next table. A priority-100 flow sends the packets to connection tracker based on a hint provided by the previous tables (with a match for reg0[0] == 1) by using the ct_next ; action.

*Ingress table 6:***from-lport***ACLs*

Logical flows in this table closely reproduce those in the **ACL** table in the **OVN_Northbound** database for the **from-lport** direction. The **priority** values from the **ACL** table have a limited range and have 1000 added to them to leave room for OVN default flows at both higher and lower priorities.

- **allow** ACLs translate into logical flows with the **next**; action. If there are any stateful ACLs on this datapath, then **allow** ACLs translate to **ct_commit**; **next**; (which acts as a hint for the next tables to commit the connection to conntrack),
- allow-related ACLs translate into logical flows with the ct_commit(ct_label=0/1); next; actions for new connections and reg0[1] = 1; next; for existing connections.
- Other ACLs translate to **drop**; for new or untracked connections and **ct_com-mit(ct_label=1/1)**; for known connections. Setting **ct_label** marks a connection as one that was previously allowed, but should no longer be allowed due to a policy change.

This table also contains a priority 0 flow with action **next**;, so that ACLs allow packets by default. If the logical datapath has a statetful ACL, the following flows will also be added:

- A priority-1 flow that sets the hint to commit IP traffic to the connection tracker (with action reg0[1] = 1; next;). This is needed for the default allow policy because, while the initiator's direction may not have any stateful rules, the server's may and then its return traffic would not be known and marked as invalid.
- A priority-65535 flow that allows any traffic in the reply direction for a connection that has been committed to the connection tracker (i.e., established flows), as long as the committed flow does not have ct_label.blocked set. We only handle traffic in the reply direction here because we want all packets going in the request direction to still go through the flows that implement the currently defined policy based on ACLs. If a connection is no longer allowed by policy, ct_label.blocked will get set and packets in the reply direction will no longer be allowed, either.
- A priority-65535 flow that allows any traffic that is considered related to a committed flow in the connection tracker (e.g., an ICMP Port Unreachable from a non-listening UDP port), as long as the committed flow does not have ct_label.blocked set.
- A priority-65535 flow that drops all traffic marked by the connection tracker as invalid.
- A priority-65535 flow that drops all traffic in the reply direction with ct_label.blocked set meaning that the connection should no longer be allowed due to a policy change. Packets in the request direction are skipped here to let a newly created ACL re-allow this connection.
- A priority 34000 logical flow is added for each logical switch datapath with the match **eth.dst** = E to allow the service monitor reply packet destined to **ovn-controller** with the action **next**, where E is the service monitor mac defined in the **options:svc_monitor_mac** colum of **NB_Global** table.

Ingress Table 7:from-lportQoS Marking

Logical flows in this table closely reproduce those in the **QoS** table with the **action** column set in the **OVN Northbound** database for the **from-lport** direction.

- For every qos_rules entry in a logical switch with DSCP marking enabled, a flow will be added at the priority mentioned in the QoS table.
- One priority-0 fallback flow that matches all packets and advances to the next table.

Ingress Table 8:from-lportQoS Meter

Logical flows in this table closely reproduce those in the **QoS** table with the **bandwidth** column set in the **OVN_Northbound** database for the **from-lport** direction.

- For every qos_rules entry in a logical switch with metering enabled, a flow will be added at the priority mentioned in the QoS table.
- One priority—0 fallback flow that matches all packets and advances to the next table.

Ingress Table 9: LB

It contains a priority-0 flow that simply moves traffic to the next table. For established connections a priority 100 flow matches on **ct.est && !ct.new && !ct.inv** and sets an action **reg0[2] = 1; next;** to act as a hint for table **Stateful** to send packets through connection tracker to NAT the packets. (The packet will automatically get DNATed to the same IP address as the first packet in that connection.)

Ingress Table 10: Stateful

enabled, then *args* will only contain those endpoints whose service monitor status entry in **OVN_Southbound** db is either **online** or empty.

- For all the configured load balancing rules for a switch in **OVN_Northbound** database that includes just an IP address *VIP* to match on, OVN adds a priority–110 flow. For IPv4 *VIPs*, the flow matches **ct.new && ip && ip4.dst** == *VIP*. For IPv6 *VIPs*, the flow matches **ct.new && ip && ip6.dst** == *VIP*. The action on this flow is **ct_lb**(*args*), where *args* contains comma separated IP addresses of the same address family as *VIP*.
- A priority-100 flow commits packets to connection tracker using **ct_commit**; **next**; action based on a hint provided by the previous tables (with a match for reg0[1] == 1).
- A priority-100 flow sends the packets to connection tracker using **ct_lb**; as the action based on a hint provided by the previous tables (with a match for **reg0[2] == 1**).
- A priority–0 flow that simply moves traffic to the next table.

Ingress Table 11: Pre-Hairpin

- For all configured load balancer backends a priority-2 flow that matches on traffic that needs to be hairpinned, i.e., after load balancing the destination IP matches the source IP, which sets reg0[6] = 1 and executes ct_snat(VIP) to force replies to these packets to come back through OVN.
- For all configured load balancer backends a priority-1 flow that matches on replies to hairpinned traffic, i.e., destination IP is VIP, source IP is the backend IP and source L4 port is backend port, which sets reg0[6] = 1 and executes ct snat;.
- A priority-0 flow that simply moves traffic to the next table.

Ingress Table 12: Hairpin

- A priority-1 flow that hairpins traffic matched by non-default flows in the Pre-Hairpin table. Hairpinning is done at L2, Ethernet addresses are swapped and the packets are looped back on the input port.
- A priority–0 flow that simply moves traffic to the next table.

Ingress Table 13: ARP/ND responder

This table implements ARP/ND responder in a logical switch for known IPs. The advantage of the ARP responder flow is to limit ARP broadcasts by locally responding to ARP requests without the need to send to other hypervisors. One common case is when the inport is a logical port associated with a VIF and the broadcast is responded to on the local hypervisor rather than broadcast across the whole network and responded to by the destination VM. This behavior is proxy ARP.

ARP requests arrive from VMs from a logical switch inport of type default. For this case, the logical switch proxy ARP rules can be for other VMs or logical router ports. Logical switch proxy ARP rules may be programmed both for mac binding of IP addresses on other logical switch VIF ports (which are of the default logical switch port type, representing connectivity to VMs or containers), and for mac binding of IP addresses on logical switch router type ports, representing their logical router port peers. In order to support proxy ARP for logical router ports, an IP address must be configured on the logical switch router type port, with the same value as the peer logical router port. The configured MAC addresses must match as well. When a VM sends an ARP request for a distributed logical router port and if the peer router type port of the attached logical switch does not have an IP address configured, the ARP request will be broadcast on the logical switch. One of the copies of the ARP request will go through the logical switch router type port to the logical router datapath, where the logical router ARP responder will generate a reply. The MAC binding of a distributed logical router, once learned by an associated VM, is used for all that VM's communication needing routing. Hence, the action of a VM re-arping for the mac binding of the logical router port should be rare.

Logical switch ARP responder proxy ARP rules can also be hit when receiving ARP requests externally on a L2 gateway port. In this case, the hypervisor acting as an L2 gateway, responds to the ARP request on

behalf of a destination VM.

Note that ARP requests received from **localnet** or **vtep** logical inports can either go directly to VMs, in which case the VM responds or can hit an ARP responder for a logical router port if the packet is used to resolve a logical router port next hop address. In either case, logical switch ARP responder rules will not be hit. It contains these logical flows:

- Priority-100 flows to skip the ARP responder if inport is of type localnet or vtep and advances directly to the next table. ARP requests sent to localnet or vtep ports can be received by multiple hypervisors. Now, because the same mac binding rules are downloaded to all hypervisors, each of the multiple hypervisors will respond. This will confuse L2 learning on the source of the ARP requests. ARP requests received on an inport of type router are not expected to hit any logical switch ARP responder flows. However, no skip flows are installed for these packets, as there would be some additional flow cost for this and the value appears limited.
- If inport **V** is of type **virtual** adds a priority–100 logical flow for each *P* configured in the **options:virtual-parents** column with the match

```
inport == P && && ((arp.op == 1 && arp.spa == VIP && arp.tpa == VIP) || (arp.op == 2 && arp.spa
```

and applies the action

```
bind_vport(V, inport);
```

and advances the packet to the next table.

Where *VIP* is the virtual ip configured in the column **options:virtual-ip**.

Priority-50 flows that match ARP requests to each known IP address A of every logical switch port, and respond with ARP replies directly with corresponding Ethernet address E:

```
eth.dst = eth.src;
eth.src = E;
arp.op = 2; /* ARP reply. */
arp.tha = arp.sha;
arp.sha = E;
arp.tpa = arp.spa;
arp.spa = A;
outport = inport;
flags.loopback = 1;
output;
```

These flows are omitted for logical ports (other than router ports or **localport** ports) that are down and for logical ports of type **virtual**.

• Priority–50 flows that match IPv6 ND neighbor solicitations to each known IP address *A* (and *A*'s solicited node address) of every logical switch port except of type router, and respond with neighbor advertisements directly with corresponding Ethernet address *E*:

```
nd_na {
    eth.src = E;
    ip6.src = A;
    nd.target = A;
    nd.tll = E;
    outport = inport;
    flags.loopback = 1;
    output;
```

};

Priority–50 flows that match IPv6 ND neighbor solicitations to each known IP address *A* (and *A*'s solicited node address) of logical switch port of type router, and respond with neighbor advertisements directly with corresponding Ethernet address *E*:

```
nd_na_router {
    eth.src = E;
    ip6.src = A;
    nd.target = A;
    nd.tll = E;
    outport = inport;
    flags.loopback = 1;
    output;
};
```

These flows are omitted for logical ports (other than router ports or **localport** ports) that are down and for logical ports of type **virtual**.

• Priority-100 flows with match criteria like the ARP and ND flows above, except that they only match packets from the **inport** that owns the IP addresses in question, with action **next**;. These flows prevent OVN from replying to, for example, an ARP request emitted by a VM for its own IP address. A VM only makes this kind of request to attempt to detect a duplicate IP address assignment, so sending a reply will prevent the VM from accepting the IP address that it owns.

In place of **next**;, it would be reasonable to use **drop**; for the flows' actions. If everything is working as it is configured, then this would produce equivalent results, since no host should reply to the request. But ARPing for one's own IP address is intended to detect situations where the network is not working as configured, so dropping the request would frustrate that intent.

• For each SVC_MON_SRC_IP defined in the value of the ip_port_mappings:END-POINT_IP column of Load_Balancer table, priority-110 logical flow is added with the match arp.tpa == SVC_MON_SRC_IP && && arp.op == 1 and applies the action

```
eth.dst = eth.src;
eth.src = E;
arp.op = 2; /* ARP reply. */
arp.tha = arp.sha;
arp.sha = E;
arp.tpa = arp.spa;
arp.spa = A;
outport = inport;
flags.loopback = 1;
output;
```

where *E* is the service monitor source mac defined in the **options:svc_monitor_mac** column in the **NB_Global** table. This mac is used as the source mac in the service monitor packets for the load balancer endpoint IP health checks.

SVC_MON_SRC_IP is used as the source ip in the service monitor IPv4 packets for the load balancer endpoint IP health checks.

These flows are required if an ARP request is sent for the IP SVC_MON_SRC_IP.

• For each *VIP* configured in the table **Forwarding_Group** a priority–50 logical flow is added with the match **arp.tpa** == *vip* && && arp.op == 1

and applies the action

```
eth.dst = eth.src;
eth.src = E;
arp.op = 2; /* ARP reply. */
arp.tha = arp.sha;
arp.sha = E;
arp.tpa = arp.spa;
arp.spa = A;
outport = inport;
flags.loopback = 1;
output;
```

where E is the forwarding group's mac defined in the **vmac**.

A is used as either the destination ip for load balancing traffic to child ports or as nexthop to hosts behind the child ports.

These flows are required to respond to an ARP request if an ARP request is sent for the IP *vip*.

• One priority–0 fallback flow that matches all packets and advances to the next table.

Ingress Table 14: DHCP option processing

This table adds the DHCPv4 options to a DHCPv4 packet from the logical ports configured with IPv4 address(es) and DHCPv4 options, and similarly for DHCPv6 options. This table also adds flows for the logical ports of type **external**.

A priority-100 logical flow is added for these logical ports which matches the IPv4 packet with udp.src = 68 and udp.dst = 67 and applies the action put_dhcp_opts and advances the packet to the next table.

```
reg0[3] = put_dhcp_opts(offer_ip = ip, options...);
next;
```

For DHCPDISCOVER and DHCPREQUEST, this transforms the packet into a DHCP reply, adds the DHCP offer IP *ip* and options to the packet, and stores 1 into reg0[3]. For other kinds of packets, it just stores 0 into reg0[3]. Either way, it continues to the next table.

A priority-100 logical flow is added for these logical ports which matches the IPv6 packet with udp.src = 546 and udp.dst = 547 and applies the action put_dhcpv6_opts and advances the packet to the next table.

```
reg0[3] = put_dhcpv6_opts(ia_addr = ip, options...);
next;
```

For DHCPv6 Solicit/Request/Confirm packets, this transforms the packet into a DHCPv6 Advertise/Reply, adds the DHCPv6 offer IP *ip* and options to the packet, and stores 1 into reg0[3]. For other kinds of packets, it just stores 0 into reg0[3]. Either way, it continues to the next table.

• A priority–0 flow that matches all packets to advances to table 15.

Ingress Table 15: DHCP responses

This table implements DHCP responder for the DHCP replies generated by the previous table.

• A priority 100 logical flow is added for the logical ports configured with DHCPv4 options which matches IPv4 packets with **udp.src** == 68 && udp.dst == 67 && reg0[3] == 1 and responds back to the **inport** after applying these actions. If reg0[3] is set to 1, it

means that the action **put_dhcp_opts** was successful.

```
eth.dst = eth.src;
eth.src = E;
ip4.src = S;
udp.src = 67;
udp.dst = 68;
outport = P;
flags.loopback = 1;
output;
```

where E is the server MAC address and S is the server IPv4 address defined in the DHCPv4 options. Note that **ip4.dst** field is handled by **put_dhcp_opts**.

(This terminates ingress packet processing; the packet does not go to the next ingress table.)

• A priority 100 logical flow is added for the logical ports configured with DHCPv6 options which matches IPv6 packets with udp.src == 546 && udp.dst == 547 && reg0[3] == 1 and responds back to the inport after applying these actions. If reg0[3] is set to 1, it means that the action put_dhcpv6_opts was successful.

```
eth.dst = eth.src;
eth.src = E;
ip6.dst = A;
ip6.src = S;
udp.src = 547;
udp.dst = 546;
outport = P;
flags.loopback = 1;
output;
```

where *E* is the server MAC address and *S* is the server IPv6 LLA address generated from the **server_id** defined in the DHCPv6 options and *A* is the IPv6 address defined in the logical port's addresses column.

(This terminates packet processing; the packet does not go on the next ingress table.)

• A priority–0 flow that matches all packets to advances to table 16.

Ingress Table 16 DNS Lookup

This table looks up and resolves the DNS names to the corresponding configured IP address(es).

A priority-100 logical flow for each logical switch datapath if it is configured with DNS records, which matches the IPv4 and IPv6 packets with udp.dst = 53 and applies the action dns_lookup and advances the packet to the next table.

```
reg0[4] = dns_lookup(); next;
```

For valid DNS packets, this transforms the packet into a DNS reply if the DNS name can be resolved, and stores 1 into reg0[4]. For failed DNS resolution or other kinds of packets, it just stores 0 into reg0[4]. Either way, it continues to the next table.

Ingress Table 17 DNS Responses

This table implements DNS responder for the DNS replies generated by the previous table.

• A priority-100 logical flow for each logical switch datapath if it is configured with DNS records, which matches the IPv4 and IPv6 packets with **udp.dst** = 53 && reg0[4] == 1 and responds back to the **inport** after applying these actions. If reg0[4] is set to 1, it

means that the action dns_lookup was successful.

```
eth.dst <-> eth.src;
ip4.src <-> ip4.dst;
udp.dst = udp.src;
udp.src = 53;
outport = P;
flags.loopback = 1;
output;
```

(This terminates ingress packet processing; the packet does not go to the next ingress table.)

Ingress table 18 External ports

Traffic from the **external** logical ports enter the ingress datapath pipeline via the **localnet** port. This table adds the below logical flows to handle the traffic from these ports.

A priority-100 flow is added for each external logical port which doesn't reside on a
chassis to drop the ARP/IPv6 NS request to the router IP(s) (of the logical switch) which
matches on the inport of the external logical port and the valid eth.src address(es) of the
external logical port.

This flow guarantees that the ARP/NS request to the router IP address from the external ports is responded by only the chassis which has claimed these external ports. All the other chassis, drops these packets.

• A priority–0 flow that matches all packets to advances to table 19.

Ingress Table 19 Destination Lookup

This table implements switching behavior. It contains these logical flows:

- A priority-110 flow with the match **eth.src** == E for all logical switch datapaths and applies the action **handle_svc_check(inport)**. Where E is the service monitor mac defined in the **options:svc_monitor_mac** colum of **NB_Global** table.
- A priority-100 flow that punts all IGMP/MLD packets to ovn-controller if multicast snooping is enabled on the logical switch. The flow also forwards the IGMP/MLD packets to the MC_MROUTER_STATIC multicast group, which ovn-northd populates with all the logical ports that have options:mcast_flood_reports='true'.
- Priority-90 flows that forward registered IP multicast traffic to their corresponding multicast group, which ovn-northd creates based on learnt IGMP_Group entries. The flows also forward packets to the MC_MROUTER_FLOOD multicast group, which ovn-nortdh populates with all the logical ports that are connected to logical routers with options:mcast_relay='true'.
- A priority-85 flow that forwards all IP multicast traffic destined to 224.0.0.X to the MC_FLOOD multicast group, which ovn-northd populates with all enabled logical ports.
- A priority-85 flow that forwards all IP multicast traffic destined to reserved multicast IPv6 addresses (RFC 4291, 2.7.1, e.g., Solicited-Node multicast) to the MC_FLOOD multicast group, which ovn-northd populates with all enabled logical ports.
- A priority-80 flow that forwards all unregistered IP multicast traffic to the MC_STATIC multicast group, which ovn-northd populates with all the logical ports that have options :mcast_flood='true'. The flow also forwards unregistered IP multicast traffic to the MC_MROUTER_FLOOD multicast group, which ovn-northd populates with all the logical ports connected to logical routers that have options :mcast_relay='true'.

- A priority-80 flow that drops all unregistered IP multicast traffic if **other_config** :mcast_snoop='true' and **other_config** :mcast_flood_unregistered='false' and the switch is not connected to a logical router that has **options** :mcast_relay='true' and the switch doesn't have any logical port with **options** :mcast_flood='true'.
- Priority-80 flows for each port connected to a logical router matching self originated GARP/ARP request/ND packets. These packets are flooded to the MC_FLOOD which contains all logical ports.
- Priority-75 flows for each IP address/VIP/NAT address owned by a router port connected
 to the switch. These flows match ARP requests and ND packets for the specific IP
 addresses. Matched packets are forwarded only to the router that owns the IP address.
- A priority-70 flow that outputs all packets with an Ethernet broadcast or multicast **eth.dst** to the **MC_FLOOD** multicast group.
- One priority–50 flow that matches each known Ethernet address against **eth.dst** and outputs the packet to the single associated output port.

For the Ethernet address on a logical switch port of type **router**, when that logical switch port's **addresses** column is set to **router** and the connected logical router port specifies a **redirect–chassis**:

- The flow for the connected logical router port's Ethernet address is only programmed on the redirect-chassis.
- If the logical router has rules specified in **nat** with **external_mac**, then those addresses are also used to populate the switch's destination lookup on the chassis where **logical port** is resident.

For the Ethernet address on a logical switch port of type **router**, when that logical switch port's **addresses** column is set to **router** and the connected logical router port specifies a **reside-on-redirect-chassis** and the logical router to which the connected logical router port belongs to has a **redirect-chassis** distributed gateway logical router port:

• The flow for the connected logical router port's Ethernet address is only programmed on the **redirect–chassis**.

For each forwarding group configured on the logical switch datapath, a priority–50 flow that matches on **eth.dst** == VIP

with an action of **fwd_group(childports=***args*), where *args* contains comma separated logical switch child ports to load balance to. If **liveness** is enabled, then action also includes **liveness=true**.

One priority-0 fallback flow that matches all packets and outputs them to the
 MC_UNKNOWN multicast group, which ovn-northd populates with all enabled logical
 ports that accept unknown destination packets. As a small optimization, if no logical
 ports accept unknown destination packets, ovn-northd omits this multicast group and
 logical flow.

Egress Table 0: Pre-LB

This table is similar to ingress table **Pre-LB**. It contains a priority-0 flow that simply moves traffic to the next table. Moreover it contains a priority-110 flow to move IPv6 Neighbor Discovery traffic to the next table. If any load balancing rules exist for the datapath, a priority-100 flow is added with a match of **ip** and action of **reg0[0] = 1**; **next**; to act as a hint for table **Pre-stateful** to send IP packets to the connection tracker for packet de-fragmentation.

This table also has a priority-110 flow with the match **eth.src** == E for all logical switch datapaths to move traffic to the next table. Where E is the service monitor mac defined in the **options:svc_monitor_mac** colum of **NB_Global** table.

Egress Table 1:to-lportPre-ACLs

This is similar to ingress table **Pre-ACLs** except for **to-lport** traffic.

This table also has a priority-110 flow with the match **eth.src** == E for all logical switch datapaths to move traffic to the next table. Where E is the service monitor mac defined in the **options:svc_monitor_mac** colum of **NB_Global** table.

Egress Table 2: Pre-stateful

This is similar to ingress table **Pre-stateful**.

Egress Table 3: LB

This is similar to ingress table **LB**.

Egress Table 4:to-lportACLs

This is similar to ingress table **ACLs** except for **to-lport** ACLs.

In addition, the following flows are added.

- A priority 34000 logical flow is added for each logical port which has DHCPv4 options
 defined to allow the DHCPv4 reply packet and which has DHCPv6 options defined to
 allow the DHCPv6 reply packet from the Ingress Table 15: DHCP responses.
- A priority 34000 logical flow is added for each logical switch datapath configured with DNS records with the match **udp.dst** = **53** to allow the DNS reply packet from the **Ingress Table 17: DNS responses**.
- A priority 34000 logical flow is added for each logical switch datapath with the match **eth.src** = *E* to allow the service monitor request packet generated by **ovn-controller** with the action **next**, where *E* is the service monitor mac defined in the **options:svc_monitor_mac** colum of **NB_Global** table.

Egress Table 5:to-lportQoS Marking

This is similar to ingress table **QoS marking** except they apply to **to-lport** QoS rules.

Egress Table 6:to-lportQoS Meter

This is similar to ingress table **QoS meter** except they apply to **to-lport** QoS rules.

Egress Table 7: Stateful

This is similar to ingress table **Stateful** except that there are no rules added for load balancing new connections.

Egress Table 8: Egress Port Security - IP

This is similar to the port security logic in table Ingress Port Security – IP except that outport, eth.dst, ip4.dst and ip6.dst are checked instead of inport, eth.src, ip4.src and ip6.src

Egress Table 9: Egress Port Security - L2

This is similar to the ingress port security logic in ingress table **Admission Control and Ingress Port Security – L2**, but with important differences. Most obviously, **outport** and **eth.dst** are checked instead of **inport** and **eth.src**. Second, packets directed to broadcast or multicast **eth.dst** are always accepted instead of being subject to the port security rules; this is implemented through a priority–100 flow that matches on **eth.mcast** with action **output**; Moreover, to ensure that even broadcast and multicast packets are not delivered to disabled logical ports, a priority–150 flow for each disabled logical **outport** overrides the priority–100 flow with a **drop**; action. Finally if egress qos has been enabled on a localnet port, the outgoing queue id is set through **set_queue** action. Please remember to mark the corresponding physical interface with **ovn-egress-iface** set to true in **external_ids**

Logical Router Datapaths

Logical router datapaths will only exist for **Logical_Router** rows in the **OVN_Northbound** database that do not have **enabled** set to **false**

Ingress Table 0: L2 Admission Control

This table drops packets that the router shouldn't see at all based on their Ethernet headers. It contains the following flows:

- Priority-100 flows to drop packets with VLAN tags or multicast Ethernet source addresses.
- For each enabled router port P with Ethernet address E, a priority–50 flow that matches inport == P && (eth.mcast || eth.dst == E), with action next;

For the gateway port on a distributed logical router (where one of the logical router ports specifies a **redirect-chassis**), the above flow matching **eth.dst** == E is only programmed on the gateway port instance on the **redirect-chassis**.

• For each **dnat_and_snat** NAT rule on a distributed router that specifies an external Ethernet address *E*, a priority–50 flow that matches **inport** == *GW* && eth.dst == *E*, where *GW* is the logical router gateway port, with action **next**;

This flow is only programmed on the gateway port instance on the chassis where the **logical port** specified in the NAT rule resides.

Other packets are implicitly dropped.

Ingress Table 1: Neighbor lookup

For ARP and IPv6 Neighbor Discovery packets, this table looks into the **MAC_Binding** records to determine if OVN needs to learn the mac bindings. Following flows are added:

• For each router port P that owns IP address A, which belongs to subnet S with prefix length L, a priority-100 flow is added which matches **inport** == P && arp.spa == S/L && arp.op == 1 (ARP request) with the following actions:

```
reg9[4] = lookup_arp(inport, arp.spa, arp.sha);
next:
```

If the logical router port P is a distributed gateway router port, additional match **is_chassis_resident(cr-**P) is added so that the resident gateway chassis handles the neighbor lookup.

• A priority–100 flow which matches on ARP reply packets and applies the actions:

```
reg9[4] = lookup_arp(inport, arp.spa, arp.sha);
next:
```

 A priority-100 flow which matches on IPv6 Neighbor Discovery advertisement packet and applies the actions:

```
reg9[4] = lookup_nd(inport, nd.target, nd.tll);
next;
```

• A priority–100 flow which matches on IPv6 Neighbor Discovery solicitation packet and applies the actions:

```
reg9[4] = lookup_nd(inport, ip6.src, nd.sll);
next;
```

• A priority-0 fallback flow that matches all packets and applies the action **reg9[5] = 1**; **next**; advancing the packet to the next table.

Ingress Table 2: Neighbor learning

This table adds flows to learn the mac bindings from the ARP and IPv6 Neighbor Solicitation/Advertisement packets if ARP/ND lookup failed in the previous table.

reg9[4] will be 1 if the lookup_arp/lookup_nd in the previous table was successful.

reg9[5] will be 1 if there was no need to do the lookup.

- A priority–100 flow with the match $reg9[4] == 1 \parallel reg9[5] == 1$ and advances the packet to the next table as there is no need to learn the neighbor.
- A priority-90 flow with the match arp and applies the action put_arp(inport, arp.spa, arp.sha); next;
- A priority-90 flow with the match nd_na and applies the action put_nd(inport, nd.target, nd.tll); next;
- A priority-90 flow with the match nd_ns and applies the action put_nd(inport, ip6.src, nd.sll); next;

Ingress Table 3: IP Input

This table is the core of the logical router datapath functionality. It contains the following flows to implement very basic IP host functionality.

• For each NAT entry of a distributed logical router (with distributed gateway router port) of type **snat**, a priorirty–120 flow with the match **inport** == *P* && **ip4.src** == *A* advances the packet to the next pipeline, where *P* is the distributed logical router port and *A* is the **external_ip** set in the NAT entry. If *A* is an IPv6 address, then **ip6.src** is used for the match.

The above flow is required to handle the routing of the East/west NAT traffic.

- L3 admission control: A priority–100 flow drops packets that match any of the following:
 - ip4.src[28..31] == 0xe (multicast source)
 - **ip4.src** == **255.255.255.255** (broadcast source)
 - ip4.src == 127.0.0.0/8 || ip4.dst == 127.0.0.0/8 (localhost source or destination)
 - ip4.src == 0.0.0.0/8 || ip4.dst == 0.0.0.0/8 (zero network source or destination)
 - ip4.src or ip6.src is any IP address owned by the router, unless the packet was recirculated due to egress loopback as indicated by REG-BIT_EGRESS_LOOPBACK.
 - **ip4.src** is the broadcast address of any IP network known to the router.
- A priority-87 flow explicitly allows IPv6 multicast traffic that is supposed to reach the router pipeline (e.g., neighbor solicitations and traffic destined to the All-Routers multicast group).
- A priority-86 flow allows IP multicast traffic if options:mcast_relay='true', otherwise drops it.
- ICMP echo reply. These flows reply to ICMP echo requests received for the router's IP address. Let A be an IP address owned by a router port. Then, for each A that is an IPv4 address, a priority–90 flow matches on **ip4.dst** == A and **icmp4.type** == **8 && icmp4.code** == **0** (ICMP echo request). For each A that is an IPv6 address, a priority–90 flow matches on **ip6.dst** == A and **icmp6.type** == **128 && icmp6.code** == **0** (ICMPv6 echo request). The port of the router that receives the echo request does not matter. Also, the **ip.ttl** of the echo request packet is not checked, so it complies with RFC 1812, section 4.2.2.9. Flows for ICMPv4 echo requests use the following actions:

```
ip4.dst <-> ip4.src;
ip.ttl = 255;
icmp4.type = 0;
flags.loopback = 1;
next;
```

Flows for ICMPv6 echo requests use the following actions:

```
ip6.dst <-> ip6.src;
ip.ttl = 255;
icmp6.type = 129;
flags.loopback = 1;
next;
```

Reply to ARP requests.

These flows reply to ARP requests for the router's own IP address. The ARP requests are handled only if the requestor's IP belongs to the same subnets of the logical router port. For each router port P that owns IP address A, which belongs to subnet S with prefix length L, and Ethernet address E, a priority–90 flow matches **inport** == P && arp.spa == S/L && arp.op == 1 && arp.tpa == A (ARP request) with the following actions:

```
eth.dst = eth.src;
eth.src = E;
arp.op = 2; /* ARP reply. */
arp.tha = arp.sha;
arp.sha = E;
arp.tpa = arp.spa;
arp.spa = A;
outport = P;
flags.loopback = 1;
output;
```

For the gateway port on a distributed logical router (where one of the logical router ports specifies a **redirect-chassis**), the above flows are only programmed on the gateway port instance on the **redirect-chassis**. This behavior avoids generation of multiple ARP responses from different chassis, and allows upstream MAC learning to point to the **redirect-chassis**.

For the logical router port with the option **reside-on-redirect-chassis** set (which is centralized), the above flows are only programmed on the gateway port instance on the **redirect-chassis** (if the logical router has a distributed gateway port). This behavior avoids generation of multiple ARP responses from different chassis, and allows upstream MAC learning to point to the **redirect-chassis**.

• Reply to IPv6 Neighbor Solicitations. These flows reply to Neighbor Solicitation requests for the router's own IPv6 address and populate the logical router's mac binding table.

For each router port P that owns IPv6 address A, solicited node address S, and Ethernet address E, a priority-90 flow matches **inport** == P && **nd_ns** && **ip6.dst** == $\{A, E\}$ && **nd_target** == A with the following actions:

```
nd_na_router {
   eth.src = E;
   ip6.src = A;
   nd.target = A;
   nd.tll = E;
   outport = inport;
   flags.loopback = 1;
   output;
};
```

For the gateway port on a distributed logical router (where one of the logical router ports specifies a **redirect–chassis**), the above flows replying to IPv6 Neighbor Solicitations are only programmed on the gateway port instance on the **redirect–chassis**. This behavior avoids generation of multiple replies from different chassis, and allows upstream MAC learning to point to the **redirect–chassis**.

 These flows reply to ARP requests or IPv6 neighbor solicitation for the virtual IP addresses configured in the router for DNAT or load balancing.

IPv4: For a configured DNAT IP address or a load balancer IPv4 VIP A, for each router port P with Ethernet address E, a priority–90 flow matches **inport** == P && arp.op == 1 && arp.tpa == A (ARP request) with the following actions:

```
eth.dst = eth.src;
eth.src = E;
arp.op = 2; /* ARP reply. */
arp.tha = arp.sha;
arp.sha = E;
arp.tpa = arp.spa;
arp.spa = A;
outport = P;
flags.loopback = 1;
output;
```

If the router port *P* is a distributed gateway router port, then the **is_chassis_resident**(*P*) is also added in the match condition for the load balancer IPv4 VIP *A*.

IPv6: For a configured DNAT IP address or a load balancer IPv6 VIP A, solicited node address S, for each router port P with Ethernet address E, a priority–90 flow matches **inport** == P && nd_ns && **ip6.dst** == $\{A, S\}$ && nd.target == A with the following actions:

```
eth.dst = eth.src;
nd_na {
    eth.src = E;
    nd.tll = E;
    ip6.src = A;
    nd.target = A;
    outport = P;
    flags.loopback = 1;
    output;
}
```

If the router port *P* is a distributed gateway router port, then the **is_chassis_resident**(*P*) is also added in the match condition for the load balancer IPv6 VIP *A*.

For the gateway port on a distributed logical router with NAT (where one of the logical router ports specifies a **redirect-chassis**):

- If the corresponding NAT rule cannot be handled in a distributed manner, then
 this flow is only programmed on the gateway port instance on the redirect-chassis. This behavior avoids generation of multiple ARP responses from
 different chassis, and allows upstream MAC learning to point to the redirect-chassis.
- If the corresponding NAT rule can be handled in a distributed manner, then this
 flow is only programmed on the gateway port instance where the logical_port
 specified in the NAT rule resides.

Some of the actions are different for this case, using the **external_mac** specified in the NAT rule rather than the gateway port's Ethernet address *E*:

```
eth.src = external_mac;
arp.sha = external_mac;
or in the case of IPv6 neighbor solicition:
eth.src = external_mac;
nd.tll = external_mac;
```

This behavior avoids generation of multiple ARP responses from different chassis, and allows upstream MAC learning to point to the correct chassis.

- Priority–85 flows which drops the ARP and IPv6 Neighbor Discovery packets.
- UDP port unreachable. Priority-80 flows generate ICMP port unreachable messages in reply to UDP datagrams directed to the router's IP address, except in the special case of gateways, which accept traffic directed to a router IP for load balancing and NAT purposes.

These flows should not match IP fragments with nonzero offset.

 TCP reset. Priority-80 flows generate TCP reset messages in reply to TCP datagrams directed to the router's IP address, except in the special case of gateways, which accept traffic directed to a router IP for load balancing and NAT purposes.

These flows should not match IP fragments with nonzero offset.

 Protocol or address unreachable. Priority-70 flows generate ICMP protocol or address unreachable messages for IPv4 and IPv6 respectively in reply to packets directed to the router's IP address on IP protocols other than UDP, TCP, and ICMP, except in the special case of gateways, which accept traffic directed to a router IP for load balancing purposes.

These flows should not match IP fragments with nonzero offset.

• Drop other IP traffic to this router. These flows drop any other traffic destined to an IP address of this router that is not already handled by one of the flows above, which amounts to ICMP (other than echo requests) and fragments with nonzero offsets. For each IP address A owned by the router, a priority–60 flow matches **ip4.dst** == A or **ip6.dst** == A and drops the traffic. An exception is made and the above flow is not added if the router port's own IP address is used to SNAT packets passing through that router.

The flows above handle all of the traffic that might be directed to the router itself. The following flows (with lower priorities) handle the remaining traffic, potentially for forwarding:

- Drop Ethernet local broadcast. A priority-50 flow with match eth.bcast drops traffic destined to the local Ethernet broadcast address. By definition this traffic should not be forwarded.
- ICMP time exceeded. For each router port *P*, whose IP address is *A*, a priority–40 flow with match **inport** == *P* && ip.ttl == {0, 1} && !ip.later_frag matches packets whose TTL has expired, with the following actions to send an ICMP time exceeded reply for IPv4 and IPv6 respectively:

```
icmp4 {
    icmp4.type = 11; /* Time exceeded. */
    icmp4.code = 0; /* TTL exceeded in transit. */
    ip4.dst = ip4.src;
    ip4.src = A;
    ip.ttl = 255;
    next;
```

```
};
icmp6 {
    icmp6.type = 3; /* Time exceeded. */
    icmp6.code = 0; /* TTL exceeded in transit. */
    ip6.dst = ip6.src;
    ip6.src = A;
    ip.ttl = 255;
    next;
};
```

- TTL discard. A priority-30 flow with match **ip.ttl** == {0, 1} and actions **drop**; drops other packets whose TTL has expired, that should not receive a ICMP error reply (i.e. fragments with nonzero offset).
- Next table. A priority–0 flows match all packets that aren't already handled and uses actions **next**; to feed them to the next table.

Ingress Table 4: DEFRAG

This is to send packets to connection tracker for tracking and defragmentation. It contains a priority-0 flow that simply moves traffic to the next table. If load balancing rules with virtual IP addresses (and ports) are configured in **OVN_Northbound** database for a Gateway router, a priority-100 flow is added for each configured virtual IP address *VIP*. For IPv4 *VIPs* the flow matches **ip && ip4.dst** == *VIP*. For IPv6 *VIPs*, the flow matches **ip && ip6.dst** == *VIP*. The flow uses the action **ct_next**; to send IP packets to the connection tracker for packet de-fragmentation and tracking before sending it to the next table.

Ingress Table 5: UNSNAT

This is for already established connections' reverse traffic. i.e., SNAT has already been done in egress pipeline and now the packet has entered the ingress pipeline as part of a reply. It is unSNATted here.

Ingress Table 5: UNSNAT on Gateway Routers

• If the Gateway router has been configured to force SNAT any previously DNATted packets to B, a priority–110 flow matches **ip && ip4.dst** == B or **ip && ip6.dst** == B with an action **ct snat**;

If the Gateway router has been configured to force SNAT any previously load-balanced packets to B, a priority-100 flow matches **ip && ip4.dst** == B or **ip && ip6.dst** == B with an action **ct_snat**;

For each NAT configuration in the OVN Northbound database, that asks to change the source IP address of a packet from A to B, a priority-90 flow matches **ip && ip4.dst** == B or **ip && ip6.dst** == B with an action **ct_snat**; . If the NAT rule is of type dnat_and_snat and has **stateless=true** in the options, then the action would be **ip4/6.dst=** B.

A priority–0 logical flow with match 1 has actions **next**;.

Ingress Table 5: UNSNAT on Distributed Routers

• For each configuration in the OVN Northbound database, that asks to change the source IP address of a packet from A to B, a priority-100 flow matches ip && ip4.dst == B && inport == GW or ip && ip6.dst == B && inport == GW where GW is the logical router gateway port, with an action ct_snat;. If the NAT rule is of type dnat_and_snat and has stateless=true in the options, then the action would be ip4/6.dst=(B).

If the NAT rule cannot be handled in a distributed manner, then the priority–100 flow above is only programmed on the **redirect–chassis**.

A priority-0 logical flow with match 1 has actions **next**;

Ingress Table 6: DNAT

Packets enter the pipeline with destination IP address that needs to be DNATted from a virtual IP address to a real IP address. Packets in the reverse direction needs to be unDNATed.

Ingress Table 6: Load balancing DNAT rules

Following load balancing DNAT flows are added for Gateway router or Router with gateway port. These flows are programmed only on the **redirect–chassis**. These flows do not get programmed for load balancers with IPv6 *VIPs*.

- If controller_event has been enabled for all the configured load balancing rules for a Gateway router or Router with gateway port in **OVN_Northbound** database that does not have configured backends, a priority–130 flow is added to trigger ovn-controller events whenever the chassis receives a packet for that particular VIP. If **event–elb** meter has been previously created, it will be associated to the empty_lb logical flow
- For all the configured load balancing rules for a Gateway router or Router with gateway port in **OVN_Northbound** database that includes a L4 port *PORT* of protocol *P* and IPv4 or IPv6 address *VIP*, a priority–120 flow that matches on **ct.new && ip && ip4.dst** == *VIP* && *P* && *P*.**dst** == *PORT*
 - (**ip6.dst** == *VIP* in the IPv6 case) with an action of **ct_lb**(*args*), where *args* contains comma separated IPv4 or IPv6 addresses (and optional port numbers) to load balance to. If the router is configured to force SNAT any load-balanced packets, the above action will be replaced by **flags.force_snat_for_lb** = 1; **ct_lb**(*args*);. If health check is enabled, then *args* will only contain those endpoints whose service monitor status entry in **OVN_Southbound** db is either **online** or empty.
- For all the configured load balancing rules for a router in **OVN_Northbound** database that includes a L4 port *PORT* of protocol *P* and IPv4 or IPv6 address *VIP*, a priority–120 flow that matches on **ct.est && ip && ip4.dst** == *VIP* **&&** *P* **&&** *P*.**dst** == *PORT* (**ip6.dst** == *VIP* in the IPv6 case) with an action of **ct_dnat**;. If the router is configured to force SNAT any load-balanced packets, the above action will be replaced by **flags.force_snat_for_lb** = 1; **ct_dnat**;.
- For all the configured load balancing rules for a router in **OVN_Northbound** database that includes just an IP address *VIP* to match on, a priority–110 flow that matches on **ct.new && ip && ip4.dst** == *VIP* (**ip6.dst** == *VIP* in the IPv6 case) with an action of **ct_lb**(args), where args contains comma separated IPv4 or IPv6 addresses. If the router is configured to force SNAT any load-balanced packets, the above action will be replaced by **flags.force_snat_for_lb** = 1; **ct_lb**(args);
- For all the configured load balancing rules for a router in **OVN_Northbound** database that includes just an IP address *VIP* to match on, a priority–110 flow that matches on **ct.est && ip && ip4.dst** == *VIP* (or **ip6.dst** == *VIP*) with an action of **ct_dnat**;. If the router is configured to force SNAT any load-balanced packets, the above action will be replaced by **flags.force_snat_for_lb** = 1; **ct_dnat**;.

Ingress Table 6: DNAT on Gateway Routers

- For each configuration in the OVN Northbound database, that asks to change the destination IP address of a packet from A to B, a priority–100 flow matches **ip && ip4.dst** == A or **ip && ip6.dst** == A with an action **flags.loopback** = 1; **ct_dnat**(B);. If the Gateway router is configured to force SNAT any DNATed packet, the above action will be replaced by **flags.force_snat_for_dnat** = 1; **flags.loopback** = 1; **ct_dnat**(B);. If the NAT rule is of type dnat_and_snat and has **stateless=true** in the options, then the action would be **ip4/6.dst=**(B).
- For all IP packets of a Gateway router, a priority-50 flow with an action flags.loopback = 1; ct_dnat;.
- A priority-0 logical flow with match 1 has actions **next**;

Ingress Table 6: DNAT on Distributed Routers

On distributed routers, the DNAT table only handles packets with destination IP address that needs to be DNATted from a virtual IP address to a real IP address. The unDNAT processing in the reverse direction is handled in a separate table in the egress pipeline.

For each configuration in the OVN Northbound database, that asks to change the destination IP address of a packet from A to B, a priority-100 flow matches **ip && ip4.dst** == B **&& inport** == GW, where GW is the logical router gateway port, with an action **ct_dnat**(B);. The match will include **ip6.dst** == B in the IPv6 case. If the NAT rule is of type dnat_and_snat and has **stateless=true** in the options, then the action would be **ip4/6.dst=**(B).

If the NAT rule cannot be handled in a distributed manner, then the priority–100 flow above is only programmed on the **redirect–chassis**.

A priority–0 logical flow with match 1 has actions **next**;.

Ingress Table 7: IPv6 ND RA option processing

A priority-50 logical flow is added for each logical router port configured with IPv6 ND RA options which matches IPv6 ND Router Solicitation packet and applies the action put_nd_ra_opts and advances the packet to the next table.

```
reg0[5] = put_nd_ra_opts(options);next;
```

For a valid IPv6 ND RS packet, this transforms the packet into an IPv6 ND RA reply and sets the RA options to the packet and stores 1 into reg0[5]. For other kinds of packets, it just stores 0 into reg0[5]. Either way, it continues to the next table.

• A priority–0 logical flow with match 1 has actions **next**;.

Ingress Table 8: IPv6 ND RA responder

This table implements IPv6 ND RA responder for the IPv6 ND RA replies generated by the previous table.

A priority-50 logical flow is added for each logical router port configured with IPv6 ND RA options which matches IPv6 ND RA packets and reg0[5] == 1 and responds back to the inport after applying these actions. If reg0[5] is set to 1, it means that the action put_nd_ra_opts was successful.

```
eth.dst = eth.src;
eth.src = E;
ip6.dst = ip6.src;
ip6.src = I;
outport = P;
flags.loopback = 1;
output;
```

where E is the MAC address and I is the IPv6 link local address of the logical router port.

(This terminates packet processing in ingress pipeline; the packet does not go to the next ingress table.)

• A priority-0 logical flow with match 1 has actions **next**;

Ingress Table 9: IP Routing

A packet that arrives at this table is an IP packet that should be routed to the address in **ip4.dst** or **ip6.dst**. This table implements IP routing, setting **reg0** (or **xxreg0** for IPv6) to the next-hop IP address (leaving **ip4.dst** or **ip6.dst**, the packet's final destination, unchanged) and advances to the next table for ARP resolution. It also sets **reg1** (or **xxreg1**) to the IP address owned by the selected router port (ingress table **ARP Request** will generate an ARP request, if needed, with **reg0** as the target protocol address and **reg1** as the source protocol address).

For ECMP routes, i.e. multiple static routes with same policy and prefix but different nexthops, the above actions are deferred to next table. This table, instead, is responsible for determine the ECMP group id and select a member id within the group based on 5-tuple hashing. It stores group id in **reg8[0..15]** and member id in **reg8[16..31]**.

This table contains the following logical flows:

- Priority-500 flows that match IP multicast traffic destined to groups registered on any of
 the attached switches and sets **outport** to the associated multicast group that will eventually flood the traffic to all interested attached logical switches. The flows also decrement
 TTL.
- Priority-450 flow that matches unregistered IP multicast traffic and sets outport to the MC_STATIC multicast group, which ovn-northd populates with the logical ports that have options:mcast_flood='true'.
- For distributed logical routers where one of the logical router ports specifies a redirect-chassis, a priority-400 logical flow for each dnat_and_snat NAT rules configured. These flows will allow to properly forward traffic to the external connections if available and avoid sending it through the tunnel. Assuming the following NAT rule has been configured:

```
external_ip = A;
external_mac = B;
logical_ip = C;

the following action will be applied:
ip.ttl--;
reg0 = ip.dst;
reg1 = A;
eth.src = B;
outport = router-port;
next;
```

• IPv4 routing table. For each route to IPv4 network N with netmask M, on router port P with IP address A and Ethernet address E, a logical flow with match **ip4.dst** == N/M, whose priority is **400** + the number of 1-bits in M if the router port is not a distributed gateway port, else the priority is the number of 1-bits in M, has the following actions:

```
ip.ttl--;
reg8[0..15] = 0;
reg0 = G;
reg1 = A;
eth.src = E;
outport = P;
flags.loopback = 1;
next;
```

(Ingress table 1 already verified that **ip.ttl—**; will not yield a TTL exceeded error.)

If the route has a gateway, G is the gateway IP address. Instead, if the route is from a configured static route, G is the next hop IP address. Else it is **ip4.dst**.

• IPv6 routing table. For each route to IPv6 network N with netmask M, on router port P with IP address A and Ethernet address E, a logical flow with match in CIDR notation **ip6.dst** == N/M, whose priority is the integer value of M, has the following actions:

```
ip.ttl--;
reg8[0..15] = 0;
xxreg0 = G;
xxreg1 = A;
eth.src = E;
outport = P;
flags.loopback = 1;
next;
```

(Ingress table 1 already verified that **ip.ttl—**; will not yield a TTL exceeded error.)

If the route has a gateway, G is the gateway IP address. Instead, if the route is from a configured static route, G is the next hop IP address. Else it is **ip6.dst**.

If the address A is in the link-local scope, the route will be limited to sending on the ingress port.

 For ECMP routes, they are grouped by policy and prefix. An unique id (non-zero) is assigned to each group, and each member is also assigned an unique id (non-zero) within each group.

For each IPv4/IPv6 ECMP group with group id GID and member ids MID1, MID2, ..., a logical flow with match in CIDR notation **ip4.dst** == N/M, or **ip6.dst** == N/M, whose priority is the integer value of M, has the following actions:

```
ip.ttl--;
flags.loopback = 1;
reg8[0..15] = GID;
select(reg8[16..31], MID1, MID2, ...);
```

Ingress Table 10: IP ROUTING ECMP

This table implements the second part of IP routing for ECMP routes following the previous table. If a packet matched a ECMP group in the previous table, this table matches the group id and member id stored from the previous table, setting **reg0** (or **xxreg0** for IPv6) to the next-hop IP address (leaving **ip4.dst** or **ip6.dst**, the packet's final destination, unchanged) and advances to the next table for ARP resolution. It also sets **reg1** (or **xxreg1**) to the IP address owned by the selected router port (ingress table **ARP Request** will generate an ARP request, if needed, with **reg0** as the target protocol address and **reg1** as the source protocol address).

This table contains the following logical flows:

- A priority-150 flow that matches reg8[0..15] == 0 with action **next**; directly bypasses packets of non-ECMP routes.
- For each member with ID *MID* in each ECMP group with ID *GID*, a priority–100 flow with match reg8[0..15] == *GID* && reg8[16..31] == *MID* has following actions:

```
[xx]reg0 = G;
[xx]reg1 = A;
eth.src = E;
outport = P;
```

Ingress Table 12: ARP/ND Resolution

Any packet that reaches this table is an IP packet whose next-hop IPv4 address is in **reg0** or IPv6 address is in **xxreg0**. (**ip4.dst** or **ip6.dst** contains the final destination.) This table resolves the IP address in **reg0** (or **xxreg0**) into an output port in **outport** and an Ethernet address in **eth.dst**, using the following flows:

- A priority-500 flow that matches IP multicast traffic that was allowed in the routing pipeline. For this kind of traffic the **outport** was already set so the flow just advances to the next table.
- Static MAC bindings. MAC bindings can be known statically based on data in the OVN_Northbound database. For router ports connected to logical switches, MAC bindings can be known statically from the addresses column in the Logical_Switch_Port table. For router ports connected to other logical routers, MAC bindings can be known statically from the mac and networks column in the Logical_Router_Port table.

For each IPv4 address A whose host is known to have Ethernet address E on router port P, a priority–100 flow with match **outport** === P && reg0 == A has actions **eth.dst** = E; next:

For each virtual ip A configured on a logical port of type **virtual** and its virtual parent set in its corresponding **Port_Binding** record and the virtual parent with the Ethernet address E and the virtual ip is reachable via the router port P, a priority–100 flow with match **outport** === P && reg0 == A has actions eth.dst = E; next;

For each virtual ip A configured on a logical port of type **virtual** and its virtual parent **not** set in its corresponding **Port_Binding** record and the virtual ip A is reachable via the router port P, a priority–100 flow with match **outport** === P && **reg0** == A has actions **eth.dst** = 00:00:00:00:00:00:00; **next**;. This flow is added so that the ARP is always resolved for the virtual ip A by generating ARP request and **not** consulting the MAC_Binding table as it can have incorrect value for the virtual ip A.

For each IPv6 address A whose host is known to have Ethernet address E on router port P, a priority-100 flow with match **outport** === P && xxreg0 == A has actions **eth.dst** = E; **next**;

For each logical router port with an IPv4 address A and a mac address of E that is reachable via a different logical router port P, a priority–100 flow with match **outport** === P && reg0 == A has actions eth.dst = E; next;.

For each logical router port with an IPv6 address A and a mac address of E that is reachable via a different logical router port P, a priority–100 flow with match **outport ===** P && xxreg0 == A has actions eth.dst = E; next;.

Static MAC bindings from NAT entries. MAC bindings can also be known for the entries
in the NAT table. Below flows are programmed for distributed logical routers i.e with a
distributed router port.

For each row in the **NAT** table with IPv4 address A in the **external_ip** column of **NAT** table, a priority–100 flow with the match **outport** === P && **reg0** == A has actions **eth.dst** = E; **next**;, where **P** is the distributed logical router port, E is the Ethernet address if set in the **external_mac** column of **NAT** table for of type **dnat_and_snat**, otherwise the Ethernet address of the distributed logical router port.

For IPv6 NAT entries, same flows are added, but using the register **xxreg0** for the match.

Dynamic MAC bindings. These flows resolve MAC-to-IP bindings that have become
known dynamically through ARP or neighbor discovery. (The ingress table ARP
Request will issue an ARP or neighbor solicitation request for cases where the binding is
not yet known.)

A priority-0 logical flow with match **ip4** has actions **get_arp(outport, reg0); next;**.

A priority-0 logical flow with match **ip6** has actions **get_nd(outport, xxreg0)**; **next**;.

• For logical router port with redirect-chassis and redirect-type being set as **bridged**, a priority–50 flow will match **outport** == "ROUTER_PORT" and !is_chassis_resident ("cr-ROUTER_PORT") has actions **eth.dst** = *E*; **next**;, where *E* is the ethernet address of the logical router port.

Ingress Table 13: Check packet length

For distributed logical routers with distributed gateway port configured with **options:gateway_mtu** to a valid integer value, this table adds a priority-50 logical flow with the match **ip4 && outport** == GW_PORT where GW_PORT is the distributed gateway router port and applies the action **check_pkt_larger** and advances the packet to the next table.

```
REGBIT PKT LARGER = check pkt larger(L); next;
```

where L is the packet length to check for. If the packet is larger than L, it stores 1 in the register bit **REG-BIT_PKT_LARGER**. The value of L is taken from **options:gateway_mtu** column of **Logical_Router_Port** row.

This table adds one priority-0 fallback flow that matches all packets and advances to the next table.

Ingress Table 14: Handle larger packets

For distributed logical routers with distributed gateway port configured with **options:gateway_mtu** to a valid integer value, this table adds the following priority–50 logical flow for each logical router port with the match **ip4 && inport** == LRP && outport == GW_PORT && REGBIT_PKT_LARGER, where LRP is the logical router port and GW_PORT is the distributed gateway router port and applies the following action

```
icmp4 {
  icmp4.type = 3; /* Destination Unreachable. */
  icmp4.code = 4; /* Frag Needed and DF was Set. */
  icmp4.frag_mtu = M;
  eth.dst = E;
  ip4.dst = ip4.src;
  ip4.src = I;
  ip.ttl = 255;
  REGBIT_EGRESS_LOOPBACK = 1;
  next(pipeline=ingress, table=0);
};
```

- Where *M* is the (fragment MTU 58) whose value is taken from **options:gateway_mtu** column of **Logical_Router_Port** row.
- E is the Ethernet address of the logical router port.
- *I* is the IPv4 address of the logical router port.

This table adds one priority–0 fallback flow that matches all packets and advances to the next table.

Ingress Table 15: Gateway Redirect

For distributed logical routers where one of the logical router ports specifies a **redirect-chassis**, this table redirects certain packets to the distributed gateway port instance on the **redirect-chassis**. This table has the following flows:

- A priority-150 logical flow with match **outport** == GW && eth.dst == **00:00:00:00:00:00** has actions **outport** = CR; **next**;, where GW is the logical router distributed gateway port and CR is the **chassisredirect** port representing the instance of the logical router distributed gateway port on the **redirect-chassis**.
- For each NAT rule in the OVN Northbound database that can be handled in a distributed manner, a priority–200 logical flow with match **ip4.src** == *B* && outport == *GW*, where *GW* is the logical router distributed gateway port, with actions **next**;
- A priority-50 logical flow with match **outport** == GW has actions **outport** = CR; **next**;, where GW is the logical router distributed gateway port and CR is the **chassisredirect** port representing the instance of the logical router distributed gateway port on the

redirect-chassis.

• A priority-0 logical flow with match 1 has actions **next**;

Ingress Table 16: ARP Request

In the common case where the Ethernet destination has been resolved, this table outputs the packet. Otherwise, it composes and sends an ARP or IPv6 Neighbor Solicitation request. It holds the following flows:

• Unknown MAC address. A priority-100 flow for IPv4 packets with match **eth.dst** == **00:00:00:00:00** has the following actions:

```
arp {
  eth.dst = ff:ff:ff:ff:ff;
  arp.spa = reg1;
  arp.tpa = reg0;
  arp.op = 1; /* ARP request. */
  output;
};
```

```
nd_ns {
    eth.dst = E;
    ip6.dst = I
    nd.target = G;
    output;
};
```

Where E is the multicast mac derived from the Gateway IP, I is the solicited-node multicast address corresponding to the target address G.

Unknown MAC address. A priority–100 flow for IPv6 packets with match **eth.dst** == **00:00:00:00:00** has the following actions:

```
nd_ns {
    nd.target = xxreg0;
    output;
};
```

(Ingress table **IP Routing** initialized **reg1** with the IP address owned by **outport** and **(xx)reg0** with the next-hop IP address)

The IP packet that triggers the ARP/IPv6 NS request is dropped.

• Known MAC address. A priority–0 flow with match 1 has actions output;.

Egress Table 0: UNDNAT

This is for already established connections' reverse traffic. i.e., DNAT has already been done in ingress pipeline and now the packet has entered the egress pipeline as part of a reply. For NAT on a distributed router, it is unDNATted here. For Gateway routers, the unDNAT processing is carried out in the ingress DNAT table.

• For all the configured load balancing rules for a router with gateway port in **OVN_North-bound** database that includes an IPv4 address **VIP**, for every backend IPv4 address *B* defined for the **VIP** a priority–120 flow is programmed on **redirect–chassis** that matches **ip && ip4.src** == *B* **&& outport** == *GW*, where *GW* is the logical router gateway port with an action **ct_dnat**; If the backend IPv4 address *B* is also configured with L4 port

PORT of protocol P, then the match also includes **P.src** == PORT. These flows are not added for load balancers with IPv6 VIPs.

If the router is configured to force SNAT any load-balanced packets, above action will be replaced by **flags.force_snat_for_lb = 1**; **ct_dnat**;.

• For each configuration in the OVN Northbound database that asks to change the destination IP address of a packet from an IP address of A to B, a priority–100 flow matches ip && ip4.src == B && outport == GW, where GW is the logical router gateway port, with an action ct_dnat;. If the NAT rule is of type dnat_and_snat and has stateless=true in the options, then the action would be ip4/6.src= (B).

If the NAT rule cannot be handled in a distributed manner, then the priority–100 flow above is only programmed on the **redirect–chassis**.

If the NAT rule can be handled in a distributed manner, then there is an additional action **eth.src** = EA;, where EA is the ethernet address associated with the IP address A in the NAT rule. This allows upstream MAC learning to point to the correct chassis.

• A priority–0 logical flow with match 1 has actions **next**;.

Egress Table 1: SNAT

Packets that are configured to be SNATed get their source IP address changed based on the configuration in the OVN Northbound database.

A priority-120 flow to advance the IPv6 Neighbor solicitation packet to next table to skip SNAT. In the case where ovn-controller injects an IPv6 Neighbor Solicitation packet (for nd_ns action) we don't want the packet to go throught conntrack.

Egress Table 1: SNAT on Gateway Routers

• If the Gateway router in the OVN Northbound database has been configured to force SNAT a packet (that has been previously DNATted) to B, a priority-100 flow matches flags.force_snat_for_dnat == 1 && ip with an action ct_snat(B);

If the Gateway router in the OVN Northbound database has been configured to force SNAT a packet (that has been previously load-balanced) to B, a priority-100 flow matches flags.force_snat_for_lb == 1 && ip with an action ct_snat(B);

For each configuration in the OVN Northbound database, that asks to change the source IP address of a packet from an IP address of A or to change the source IP address of a packet that belongs to network A to B, a flow matches **ip && ip4.src** == A with an action **ct_snat**(B);. The priority of the flow is calculated based on the mask of A, with matches having larger masks getting higher priorities. If the NAT rule is of type dnat_and_snat and has **stateless=true** in the options, then the action would be **ip4/6.src=**(B).

A priority-0 logical flow with match 1 has actions next;.

Egress Table 1: SNAT on Distributed Routers

For each configuration in the OVN Northbound database, that asks to change the source IP address of a packet from an IP address of A or to change the source IP address of a packet that belongs to network A to B, a flow matches **ip && ip4.src** == A **&& outport** == GW, where GW is the logical router gateway port, with an action **ct_snat**(B); The priority of the flow is calculated based on the mask of A, with matches having larger masks getting higher priorities. If the NAT rule is of type dnat_and_snat and has **stateless=true** in the options, then the action would be **ip4/6.src=**(B).

If the NAT rule cannot be handled in a distributed manner, then the flow above is only programmed on the **redirect-chassis** increasing flow priority by 128 in order to be run first

If the NAT rule can be handled in a distributed manner, then there is an additional action **eth.src** = EA;, where EA is the ethernet address associated with the IP address A in the

NAT rule. This allows upstream MAC learning to point to the correct chassis.

A priority-0 logical flow with match 1 has actions **next**;

Egress Table 2: Egress Loopback

For distributed logical routers where one of the logical router ports specifies a redirect-chassis.

While UNDNAT and SNAT processing have already occurred by this point, this traffic needs to be forced through egress loopback on this distributed gateway port instance, in order for UNSNAT and DNAT processing to be applied, and also for IP routing and ARP resolution after all of the NAT processing, so that the packet can be forwarded to the destination.

This table has the following flows:

• For each NAT rule in the OVN Northbound database on a distributed router, a priority-100 logical flow with match **ip4.dst** == *E* && outport == *GW* && is_chassis_resident(*P*), where *E* is the external IP address specified in the NAT rule, *GW* is the logical router distributed gateway port. For dnat_and_snat NAT rule, *P* is the logical port specified in the NAT rule. If **logical_port** column of **NAT** table is NOT set, then *P* is the **chassisredirect port** of *GW* with the following actions:

```
clone {
    ct_clear;
    inport = outport;
    outport = '''';
    flags = 0;
    flags.loopback = 1;
    reg0 = 0;
    reg1 = 0;
    ...
    reg9 = 0;
    REGBIT_EGRESS_LOOPBACK = 1;
    next(pipeline=ingress, table=0);
};
```

flags.loopback is set since in_port is unchanged and the packet may return back to that port after NAT processing. **REGBIT_EGRESS_LOOPBACK** is set to indicate that egress loopback has occurred, in order to skip the source IP address check against the router address.

A priority-0 logical flow with match 1 has actions **next**;

Egress Table 3: Delivery

Packets that reach this table are ready for delivery. It contains:

- Priority–110 logical flows that match IP multicast packets on each enabled logical router port and modify the Ethernet source address of the packets to the Ethernet address of the port and then execute action **output**;
- Priority–100 logical flows that match packets on each enabled logical router port, with action **output**;
